# Model of Computation: Co-processor

# Model of Computation: Co-processor

The program lives here

# Model of Computation: Co-processor

This only holds the quantum memory

# Model of Computation: Co-processor

Series of instructions/feedbacks

# The Quantum Memory

## A quantum memory

- » Contains individually addressable quantum registers (qbits)
- » State of  $n$  qbits: **complex** combination of strings of  $n$  bits
- » E.g. for  $n = 3$ :

$$\begin{array}{rcl} & -\frac{1}{2} \cdot 000 \\ + & \frac{1}{2} \cdot 001 \\ + & \frac{i}{2} \cdot 110 \\ - & \frac{i}{2} \cdot 111 \end{array}$$

- » With a norm condition.

Unlike probabilistic distributions,

all are available at the same time.

# Quantum Circuit Model

**Stream of instructions:** a series of elementary **gates** applied on the quantum memory, that are described by a **quantum circuit**.

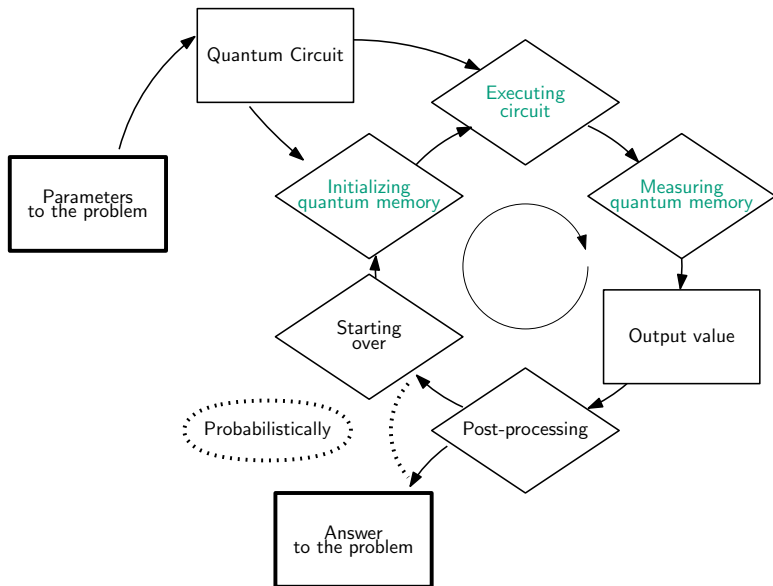

- » Each operation is **reversible**, **unitary** on the space of states
- » Wire  $\equiv$  quantum bit  $\equiv$  a **quantum register**
- » **No** “quantum loop”, “conditional stop” nor “branching point”

## Structure of (Static) Quantum Algorithms

# Structure of (Variational) Quantum Algorithms

# Quantum Algorithm, Probabilistic Algorithm

Simple probabilistic algorithm to factor 289884400687823

- » Fair draw of a number among 2, 3, 4, 5, ...
- » Test: Euclidian division
- » Found a factor: success. Otherwise: start over.

Very poor probability of success!

Shor's factorization algorithm

- » Probabilistic sampling performed with measurement
- » The quantum circuit build a “good” probability distribution.  
→ boosts factors!

Quantum programming means building a circuit

(In case you're wondering:  $315697 \cdot 918236159$ )

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 1. Quantum primitives.

### — Quantum Fourier Transform

Assuming  $\omega = 0.xy$ , we want

$$\begin{array}{rcl} & (e^{2\pi i \omega})^0 \cdot 00 \\ + & (e^{2\pi i \omega})^1 \cdot 01 \\ + & (e^{2\pi i \omega})^2 \cdot 10 \\ + & (e^{2\pi i \omega})^3 \cdot 11 \end{array} \quad \mapsto \quad 1 \cdot xy$$

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 1. Quantum primitives.

- Phase estimation.
- Amplitude amplification.

Qubit 3 in state **1** means **good**.

$$\begin{array}{rcl} & \alpha_0 \cdot 00\textcolor{red}{0} & \\ + & \alpha_1 \cdot 01\textcolor{blue}{1} & \\ + & \alpha_2 \cdot 10\textcolor{red}{0} & \\ + & \alpha_3 \cdot 11\textcolor{red}{0} & \end{array} \mapsto \begin{array}{rcl} & \alpha_0 \cdot 00\textcolor{red}{0} & \\ + & \alpha_1 \cdot 01\textcolor{blue}{1} & \\ + & \alpha_2 \cdot 10\textcolor{red}{0} & \\ + & \alpha_3 \cdot 11\textcolor{red}{0} & \end{array}$$

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 1. Quantum primitives.

- Quantum Fourier Transform
- Amplitude amplification.
- Quantum walk.

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 1. Quantum primitives.

- Quantum Fourier Transform
- Amplitude amplification.
- Quantum walk.

After 5 steps of a probabilistic walk:

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 1. Quantum primitives.

- Quantum Fourier Transform
- Amplitude amplification.
- Quantum walk.

After 5 steps of a quantum walk:

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 1. Quantum primitives.

- Quantum Fourier Transform
- Amplitude amplification
- Quantum walk
- Hamiltonian simulation
- ...

They are given as circuit templates

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 2. Oracles.

- Take a classical function  $f : \text{Bool}^n \rightarrow \text{Bool}^m$ .
- Construct

$$\begin{array}{ccc} \bar{f} : \text{Bool}^{n+m} & \longrightarrow & \text{Bool}^{n+m} \\ (x, y) & \longmapsto & (x, y \oplus f(x)) \end{array}$$

- Build the unitary  $U_f$  acting on  $n + m$  qubits computing  $\bar{f}$ .

Building the circuit depends on how  $f$  is given

## Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

### 3. Blocks of loosely-defined low-level circuits.

This is not a formal specification!

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 4. High-level operations on circuit:

— Repetition

— Inversion

— Control

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 4. High-level operations on circuit:

- Control : conditional action of a circuit

C is applied on qubits 2-4 only when qubit 1 is true:  
Suppose that C flips its input bits. Then the above circuit does

$$\begin{array}{rcl} \text{qbit} & 1 & 234 \\ \frac{1}{\sqrt{2}} & \textcolor{blue}{1} & 010 \\ + \frac{1}{\sqrt{2}} & \textcolor{red}{0} & 110 \end{array} \quad \longrightarrow \quad \begin{array}{rcl} \text{qbit} & 1 & 234 \\ \frac{1}{\sqrt{2}} & \textcolor{blue}{1} & 101 \\ + \frac{1}{\sqrt{2}} & \textcolor{red}{0} & 110 \end{array}$$

This acts as a form of “quantum test”

# Internals of Current Quantum Algorithms

The techniques used to described quantum algorithms are diverse.

## 5. Classical processing.

- Generating the circuit. . .
- Computing the input to the circuit.
- Processing classical feedback in the middle of the computation.
- Analyzing the final answer (and possibly starting over).

# Case study: BWT algorithm

- » Initialization of a register to the input node (using  $I$ )
- »  $10^6$  iterations:
  - Diffuse
  - Call oracle for red
  - Diffuse
  - Call oracle for green
  - Diffuse
  - Call oracle for blue
  - Diffuse
  - Call oracle for yellow
- » Measure the node we sit on
- » Test with  $O$  that we reached the output node.

## Case study: QLS algorithm

Considering a vector  $\vec{b}$  and the system

$$A \cdot \vec{x} = \vec{b},$$

compute the value of  $\langle \vec{x} | \vec{r} \rangle$  for some vector  $\vec{r}$ .

Practical situation: the matrix  $A$  corresponds to the finite-element approximation of the scattering problem:

## Case study: QLS algorithm

For more precision: `arXiv:1505.06552`

Three oracles:

- » for  $\vec{r}$  and for  $\vec{b}$ : input an index, output (the representation of) a complex number
- » for  $A$ : input two indexes, output also a complex number

It uses many quantum primitives

- » Amplitude estimation
- » Phase estimation
- » Amplitude amplification
- » Hamiltonian simulation

# Case study: QLS algorithm

» **Yellow:** Elementary gates.

» **Red:** Oracles.

» **Blue:** QFT's.

» **Black:** Subroutines.

» *Parameters:*

Dimensions of the space;  
Precision for each of the vectors;  
Allowed error;  
Various parameters for A. . .  
In total, 19 parameters.

# Case study: QLS algorithm

Oracle R is given by the function

```
calcRweights y nx ny lx ly k theta phi =  
  let (xc',yc') = edgetoxy y nx ny in  
  let xc = (xc'-1.0)*lx - ((fromIntegral nx)-1.0)*lx/2.0 in  
  let yc = (yc'-1.0)*ly - ((fromIntegral ny)-1.0)*ly/2.0 in  
  let (xg,yg) = itoxy y nx ny in  
  if (xg == nx) then  
    let i = (mkPolar ly (k*xc*(cos phi)))*(mkPolar 1.0 (k*yc*(sin phi)))*  
      ((sinc (k*ly*(sin phi)/2.0)) :+ 0.0) in  
    let r = ( cos(phi) :+ k*lx )*((cos (theta - phi))/lx :+ 0.0) in i * r  
  else if (xg==2*nx-1) then  
    let i = (mkPolar ly (k*xc*cos(phi)))*(mkPolar 1.0 (k*yc*sin(phi)))*  
      ((sinc (k*ly*sin(phi)/2.0)) :+ 0.0) in  
    let r = ( cos(phi) :+ (- k*lx))*((cos (theta - phi))/lx :+ 0.0) in i * r  
  else if ( (yg==1) && (xg<nx) ) then  
    let i = (mkPolar lx (k*yc*sin(phi)))*(mkPolar 1.0 (k*xc*cos(phi)))*  
      ((sinc (k*lx*(cos phi)/2.0)) :+ 0.0) in  
    let r = ( (- sin phi) :+ k*ly )*((cos(theta - phi))/ly :+ 0.0) in i * r  
  else if ( (yg==ny) && (xg<nx) ) then  
    let i = (mkPolar lx (k*yc*sin(phi)))*(mkPolar 1.0 (k*xc*cos(phi)))*  
      ((sinc (k*lx*(cos phi)/2.0)) :+ 0.0) in  
    let r = ( (- sin phi) :+ (- k*ly) )*((cos(theta - phi)/ly) :+ 0.0) in i * r  
  else 0.0 :+ 0.0
```

## Case study: circuit snippets

The algorithms create circuits whose sizes and shapes depend on the parameters. E.g. the size of the input register:

(QFT)

## Case study: circuit snippets

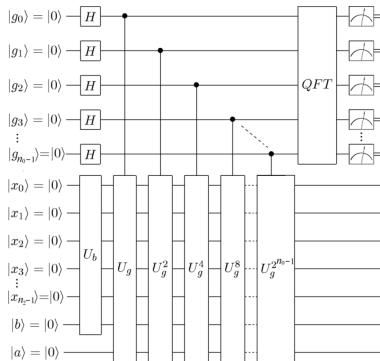

The algorithms create circuits whose sizes and shapes depend on the parameters. E.g. the size of the input register:

(diffusion step in BWT)

## Case study: circuit snippets

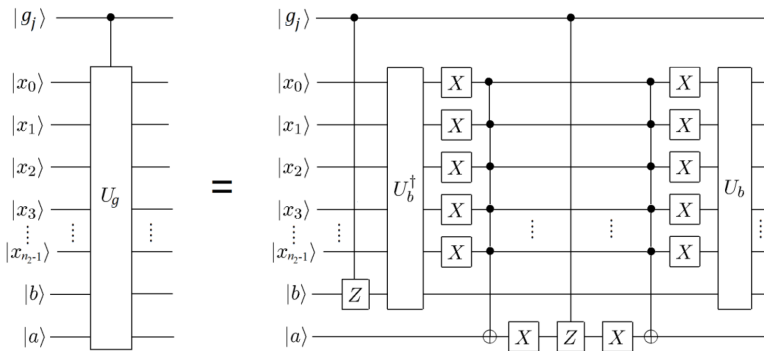

The algorithms create circuits whose sizes and shapes depend on the parameters. E.g. the size of the input register:

(piece of one subroutine of QLS)

## Case study: circuit snippets

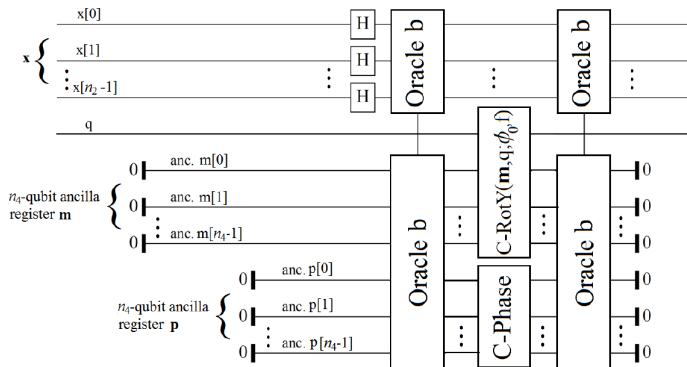

The algorithms create circuits whose sizes and shapes depend on the parameters. E.g. the size of the input register:

(the subroutine  $U_g$ )

## Case study: circuit snippets

The algorithms create circuits whose sizes and shapes depend on the parameters. E.g. the size of the input register:

(the subroutine  $U_b$ )

# Programming framework

## Two approaches

### » Circuit as a record

- One type circuit
- Qubits  $\equiv$  wire numbers
- Native: vertical/horizontal concatenation, gate addition

### » Circuit as a function

- Qubits  $\equiv$  first-order objects
- Input wires  $\equiv$  function input
- Output wires  $\equiv$  function output

# Circuits as Records

**Simplest model:** an object holding all of the circuit structure

- » Classical wires
- » Quantum wires
- » List of gates (or directed acyclic graph)
- » This is for instance QisKit/QASM model

**In this system**

- » Static circuit
- » No high-level hybrid interaction: sequence
  1. circuit generation
  2. circuit evaluation
  3. measure
  4. classical post-processing
  5. back to (1)

# Circuits as Records

## Procedural construction (QisKit)

```
q = QuantumRegister(5)
c = ClassicalRegister(1)
circ = QuantumCircuit(q,c)
```

```
circ.h(q[0])
for i in range(1,5):
    circ.cx(q[0], q[i])
circ.meas(q[4],c[0])
```

- » Static ID For registers
- » Wires are numbers
- » Gate  $\equiv$  instruction
- » Classical control: Circuit building
- » Explicit “run” of circuit

## Combinators: return a record circuit

- » `circ.control(4)`
- » `circ.inverse()`
- » `circ.append(other-circuit)`

# Circuits as Functions

A function (Quipper)

`a -> Circ b`

- » Inputs something of type `a`
- » Outputs something of type `b`
- » As a side-effect, generates a circuit snippet.

Or

- » Inputs a **value** of type `a`
- » Outputs a **computation** of type `b`

# Circuits as Functions

The circuit

can be typed with

```
Qubit -> Circ (Qubit,Qubit)
```

- » Inputs one qubit
- » Outputs a pair of qubits
- » Spits out some gates when evaluated

The gates are however encapsulated in the function

# Circuits as Functions

## Representing circuits (Quipper)

The diagram illustrates the representation of quantum circuits as functions in Quipper. It consists of two code snippets with arrows pointing from descriptive labels to specific parts of the code.

**Code Snippet 1:**

```
myCircuit :: Qubit -> Circ (Qubit, Qubit)
```

**Labels and Arrows for Snippet 1:**

- Name of circuit:** Points to `myCircuit`.
- Input: one wire:** Points to `Qubit`.
- Indeed a circuit:** Points to `Circ`.
- Two output wires:** Points to the tuple `(Qubit, Qubit)`.

**Code Snippet 2:**

```
myCircuit q = do
  ...
  ...
  return (x,y)
```

**Labels and Arrows for Snippet 2:**

- Start a procedural sequence:** Points to `do`.
- The name of the input wire:** Points to `q`.
- The two output wires:** Points to the tuple `(x,y)` in the `return` statement.

# Circuits as Functions

Procedural presentation of circuits:

```
prog :: Qubit -> Circ (Qubit,Qubit)
prog q = do
  hadamard_at q
  r <- qinit False
  qnot_at r 'controlled' q
  return (q,r)
```

# Circuits as Functions

Procedural presentation of circuits:

```
prog :: Qubit -> Circ (Qubit,Qubit)
prog q = do
  hadamard_at q
  r <- qinit False
  qnot_at r 'controlled' q
  return (q,r)
```

# Circuits as Functions

Procedural presentation of circuits:

```
prog :: Qubit -> Circ (Qubit,Qubit)
prog q = do
  hadamard_at q
  r <- qinit False
  qnot_at r 'controlled' q
  return (q,r)
```

# Circuits as Functions

Procedural presentation of circuits:

```
prog :: Qubit -> Circ (Qubit,Qubit)
prog q = do
  hadamard_at q
  r <- qinit False
  qnot_at r 'controlled' q
  return (q,r)
```

# Circuits as Functions

Procedural presentation of circuits:

```
prog :: Qubit -> Circ (Qubit,Qubit)
prog q = do
  hadamard_at q
  r <- qinit False
  qnot_at r 'controlled' q
  return (q,r)
```

# Circuits as Functions

```
import Quipper
```

```
circ ::
```

```
    Qubit -> Circ (Qubit,Qubit)
```

```
circ x = do
```

```
    y <- qinit False
```

```
    hadamard_at x
```

```
    qnot_at y 'controlled' x
```

```
    return (x,y)
```

» Qubits  $\equiv$  first-class variable

» Circuit  $\equiv$  function

» Wires  $\equiv$  inputs and outputs

» Mix classical/quantum

# Circuits as Functions

Wires do not have “fixed” location

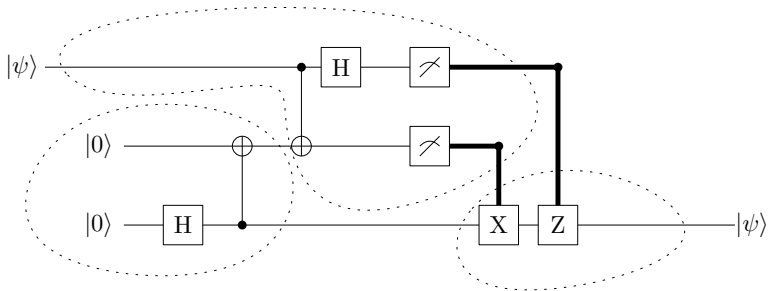

```
circ2 :: Qubit -> Circ ()  
circ2 x = do  
  (x1,x2) <- circ x  
  (y1,y2) <- circ x1  
  (z1,z2) <- circ x2  
  return ()
```

- » Qubit  $\neq$  Wire number
- » Circuits as functions: can be applied
- » More expressive types

# Circuits as Functions: Teleportation

**Exercise:** Decompose according to the dashed sections

## Circuit Combinators: exercise !

What could be the corresponding operations ?

1.  $(a \rightarrow \text{Circ } b) \rightarrow (b \rightarrow \text{Circ } c) \rightarrow (a \rightarrow \text{Circ } c)$
2.  $(a \rightarrow \text{Circ } b) \rightarrow (b \rightarrow \text{Circ } a)$
3.  $(a \rightarrow \text{Circ } b) \rightarrow (c \rightarrow \text{Circ } d)$   
 $\quad \rightarrow ((a,c) \rightarrow \text{Circ } (b,d))$
4.  $(a \rightarrow \text{Circ } b) \rightarrow ((a,\text{Qubit}) \rightarrow \text{Circ } (b,\text{Qubit}))$
5.  $(a \rightarrow \text{Circ } b) \rightarrow (\text{Qubit} \rightarrow a \rightarrow \text{Circ } (b,\text{Qubit}))$
6.  $(a \rightarrow \text{Circ } b) \rightarrow (\text{Qubit} \rightarrow a \rightarrow \text{Circ } b)$

# Circuits Combinators: Coming back to Teleportation

can be typed as

- » `EPR :: Circ (Qubit, Qubit)`
- » `Alice :: Qubit -> Qubit -> Circ (Bit, Bit)`
- » `Bob :: Qubit -> (Bit, Bit) -> Qubit`

Composing, we get

`Circ (Qubit -> Circ (Bit, Bit), (Bit, Bit) -> Circ Qubit)`

# Plan

# Families of Circuits

## A program

- » Inputs classical parameters
- » Construct a circuit from these parameters
- » Run the circuit

Circuits are parametrized families!

# Families of Circuits

## Example: QFT

# Families of Circuits

## Example: QFT

# Families of Circuits

## Example: QFT

# Families of Circuits

## Example: QFT

# Families of Circuits

With the help of lists:

The diagram illustrates the components of the `myCircuit` definition. It shows the type signature `myCircuit :: [Qubit] -> Circ [Qubit]` and the function definition `myCircuit qs = do ... return ...`. Arrows point from descriptive text to specific parts of the code: 'Name of circuit' points to `myCircuit`; 'Input a list of wires' points to the first `[Qubit]` in the type signature; 'Indeed a circuit' points to `Circ`; 'Output a list of wires' points to the second `[Qubit]`; 'Start a procedural sequence' points to `do`; 'The name of the input list' points to `qs`; and 'The output list' points to the `...` after `return`.

```
myCircuit :: [Qubit] -> Circ [Qubit]

myCircuit qs = do
  ...
  return ...
```

Annotations:

- Name of circuit
- Input a **list of wires**
- Indeed a circuit
- Output a **list of wires**
- Start a procedural sequence
- The name of the input list
- The output list

# Families of Circuits

List combinators, e.g.

$$\text{mapM} :: (a \rightarrow \text{Circ } b) \rightarrow [a] \rightarrow \text{Circ } [b]$$

Mixed presentation of circuits:

```
prog :: Qubit -> Circ (Qubit,Qubit)
```

```
prog q = do
```

```
  hadamard_at q
```

```
  r <- qinit False
```

```
  qnot_at r 'controlled' q
```

```
  return (q,r)
```

```
prog2 :: [Qubit] -> Circ [(Qubit,Qubit)]
```

```
prog2 l = mapM prog l
```

List of size 2:

# Families of Circuits

List combinators, e.g.

$$\text{mapM} :: (a \rightarrow \text{Circ } b) \rightarrow [a] \rightarrow \text{Circ } [b]$$

Mixed presentation of circuits:

```
prog :: Qubit -> Circ (Qubit,Qubit)
prog q = do
  hadamard_at q
  r <- qinit False
  qnot_at r 'controlled' q
  return (q,r)
```

```
prog2 :: [Qubit] -> Circ [(Qubit,Qubit)]
prog2 l = mapM prog l
```

List of size 10:

# Design Choices: Summary

## Requirements for coding Circuits

- » Classical structures!
- » Hierarchical Representation
- » Parametricity
- » Non-trivial Combinators

## A natural view

- » Low Key, First-Order Functions
- » Circuit construction seen as a monad

# Circuit Construction as a Monad?

**Monad:** a type constructor  $M$  equipped with

- » `return :: a -> M a`
- » `app :: M a -> (a -> M b) -> M b`

**Example:** the list monad

- » Type `[a]` : for lists of elements of type `a`
- » `return x = [x]`
- » `app [x1, x2, x3] f = (f x1) ++ (f x2) ++ (f x3)`

# Circuit Construction as a Monad?

**Monad:** a type constructor  $M$  equipped with

- » `return :: a -> M a`
- » `app :: M a -> (a -> M b) -> M b`

**Example:** state monad `M a = Int -> (a, Int)`

- » `return x = λ n . (x, n)`
- » `app g f = λ n . let (y,m) = g n in f y m`

**Special combinators**

```
get :: M Int
get = λ n . (n,n)

inc :: Int -> M ()
inc n = λ m . ((), m+n)
```

**do-notation**

```
double = do
    n <- get
    inc n
```

# Circuit Construction as a Monad?

**Monad:** a type constructor  $M$  equipped with

- » `return :: a -> M a`
- » `app :: M a -> (a -> M b) -> M b`

**Circuit monad:** `M a = GateList -> (a, GateList)`

- » `return x = λ n . (x, n)`
- » `app g f = λ n . let (y,m) = g n in f y m`

## Special combinators

`addGate :: Gate -> Wire -> M ()`

`addGate g w = λ gs . ((), [(g w) added to gs])`

`qinit :: M Wire`

`qinit = λ gs . ([fresh wire not in gs], gs)`

Interaction only performed through these combinators

# Quantum PL in the wild

## Just to name a few

- » Quipper (Academic project)
- » Q# (Microsoft)
- » Silq (ETH Zurich)

## And a wealth of Python's libraries

- » Cirq (Google)
- » myQLM (Eviden)
- » Perceval (Quandela)
- » Qiskit (IBM)
- » and one for about every single company out there

An oracle:

- » classical description  $f$  of the problem
- » turned into a reversible circuit:

$$U_f : |x\rangle|y\rangle \mapsto |x\rangle|y + f(x)\rangle$$

- » How to build  $U_f$  ?
  - Small size: circuit synthesis
  - Arithmetic or other studied functions:  
Specific (highly optimized) circuits
  - Other cases?

What about an arbitrary program, for example

```
calcRweights y nx ny lx ly k theta phi =  
  let (xc',yc') = edgetoxy y nx ny in  
  let xc = (xc'-1.0)*lx - ((fromIntegral nx)-1.0)*lx/2.0 in  
  let yc = (yc'-1.0)*ly - ((fromIntegral ny)-1.0)*ly/2.0 in  
  let (xg,yg) = itoxy y nx ny in  
  if (xg == nx) then  
    let i = (mkPolar ly (k*xc*(cos phi)))*(mkPolar 1.0 (k*yc*(sin phi)))*  
      ((sinc (k*ly*(sin phi)/2.0))+0.0) in  
    let r = ( cos(phi)+k*lx )*((cos (theta - phi))/lx+0.0) in i*r  
  else if (xg==2*nx-1) then  
    let i = (mkPolar ly (k*xc*cos(phi)))*(mkPolar 1.0 (k*yc*sin(phi)))*  
      ((sinc (k*ly*sin(phi)/2.0))+0.0) in  
    let r = ( cos(phi)+(- k*lx))*((cos (theta - phi))/lx+0.0) in i*r  
  else if ( (yg==1) and (xg<nx) ) then  
    let i = (mkPolar lx (k*yc*sin(phi)))*(mkPolar 1.0 (k*xc*cos(phi)))*  
      ((sinc (k*lx*(cos phi)/2.0))+0.0) in  
    let r = ( (- sin phi)+k*ly )*((cos(theta - phi))/ly+0.0) in i*r  
  else if ( (yg==ny) and (xg<nx) ) then  
    let i = (mkPolar lx (k*yc*sin(phi)))*(mkPolar 1.0 (k*xc*cos(phi)))*  
      ((sinc (k*lx*(cos phi)/2.0))+0.0) in  
    let r = ( (- sin phi)+(- k*ly )*((cos(theta - phi)/ly)+0.0) in i*r  
  else 0.0+0.0
```

(For QLS there was 10 matlab files of such functions)

# Problem Statement

This is the topic of this section. How to:

- » in short time
- » and automatically
- » get efficient,
- » scalable,
- » yet guaranteed
- » reversible implementation
- » of a higher-order, classical function,
- » parametrically on the input size.

# Plan

Landauer's embedding:

- » Record **all** intermediate results.
- » With  $(x \wedge y) \wedge z$

$t \mapsto x \wedge y; \quad u \mapsto t \wedge z; \quad \text{returns } u$

while retaining  $t$  as “garbage”.

- » Trace as a **partial execution**

# Basic idea

Example:  $x : \text{bool} \mapsto \text{let } f = \text{not in } (fx) \text{ and } (fx) : \text{bool}$

## Regular execution

- » Needs a concrete input, e.g.  $x = \text{true}$
- » Then: **rewriting** of the term

```
    let  $f = \text{not in } (f\text{true}) \text{ and } (f\text{true})$   
→ (not true) and (not true)  
→ false and (not true)  
→ false and false  
→ false
```

# Basic idea

Example:  $x : \text{bool} \mapsto \text{let } f = \text{not in } (fx) \text{ and } (fx) : \text{bool}$

## Trace of a partial execution

- » Start with an unknown variable  $x$
- » Then: **keep the trace** of low-level actions to be performed on  $x$

|  |  |
|--|--|
| $(\emptyset,$  | $\text{let } f = \text{not in } (fx) \text{ and } (fx))$ |
| $\rightarrow (\emptyset,$  | $(\text{not } x) \text{ and } (\text{not } x))$          |
| $\rightarrow ([y := \text{not } x]$  | $y \text{ and } (\text{not } x))$                        |
| $\rightarrow ([y \mapsto \text{not } x; z \mapsto \text{not } x],$                             | $y \text{ and } z)$                                      |
| $\rightarrow ([y \mapsto \text{not } x; z \mapsto \text{not } x; t \mapsto y \text{ and } z],$ | $t)$   |

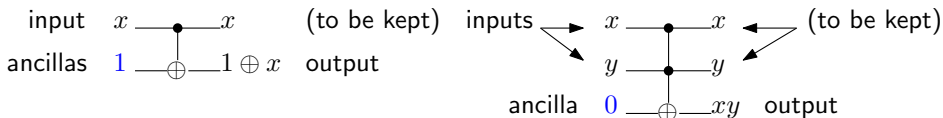

- » ...and **make this trace reversible**: Landauer's embedding

# Basic idea

Example:  $x : \text{bool} \mapsto \text{let } f = \text{not in } (fx) \text{ and } (fx) : \text{bool}$

## Trace of a partial execution

» not becomes a CNOT ; and becomes a Toffoli

» And the full trace is

# Plan

| Conclusion                                       | 128       |

# Composition Procedure

A function  $f : \text{bool} \rightarrow \text{bool}$   
is turned into a map

$$V_f : \text{bool} \rightarrow \text{circuit}(\text{bool})$$

(Note: omit garbage in type)

# Composition Procedure

A function  $\langle f, g \rangle : \text{bool} \rightarrow (\text{bool} \times \text{bool})$   
is turned into a map

$$V_{\langle f, g \rangle} : \text{bool} \rightarrow \text{circuit}(\text{bool} \times \text{bool})$$

# Composition Procedure

A function  $f : (\text{bool list}) \rightarrow \text{bool}$   
is turned into a map

$$V_f : (\text{bool list}) \rightarrow \text{circuit}(\text{bool})$$

(Parametric circuit !)

# Composition Procedure

A function  $f : A \longrightarrow B$   
is turned into a map

$$f : A \longrightarrow \text{circuit}("B")$$

# Composition Procedure

Two function  $f : A \longrightarrow B$  and  $g : B \rightarrow C$   
are turned into maps

$$V_f : A \longrightarrow \text{circuit}("B")$$

$$V_g : B \longrightarrow \text{circuit}("C")$$

Composition  $g \circ f : A \longrightarrow C$  is turned into  $A \longrightarrow \text{circuit}("C")$

# Composition Procedure

Example Try out

$$(x, y) \longmapsto \neg(\neg x) \wedge (\neg y)$$

Example Try out

$$x \longmapsto x^8$$

Assume  $x$  is a natural number modulo  $2^N$  written as a bitstring of size  $N$ , and assume that we already have a very optimized  $V$  for the multiplication.

## Oracle from $V$

We construct  $U$  as

This scheme is known as **compute-uncompute**.  
It has been implemented in Quipper.

# Plan

|  |     |
|--|-----|
| Structure of Quantum Algorithms                  | 1   |
| Design Choices for Quantum Programming Languages | 29  |
| Oracle Synthesis                                 | 59  |
| Turning Irreversible to Reversible Maps          | 62  |
| Compositional Procedure                          | 66  |
| Example and Cost Analysis                        | 73  |
| Quantum Lambda-Calculus                          | 80  |
| Quantum Control Flow                             | 113 |
| Conclusion                                       | 128 |

## Example: Adder

```
foldl :: (A → B → A) → A → [B] → A
foldl f a l = let rec g z l' = match (split l') with
                nil      ↦ z
                | (h,t)  ↦ g (f z h) t
              in g a l
```

```
bit_adder : bit → bit → bit → (bit × bit)
bit_adder carry x y =
  let majority a b c = if (xor a b) then c else a in
  let z = xor (xor carry x) y in
  let carry' = majority carry x y in ⟨carry', z⟩
```

```
adder_aux : (bit × [bit]) → (bit × bit) → (bit × [bit])
adder_aux ⟨w, cs⟩ ⟨a, b⟩ = let ⟨w', c'⟩ = bit_adder w a b in ⟨w', c'::cs⟩
```

```
adder : [bit] × [bit] → [bit]
adder x y = snd (foldl adder_aux ⟨False, nil⟩ (zip y x))
```

adder is lifted to  $[bit] \times [bit] \rightarrow \text{circuit}([bit])$ .

## Example: Adder

For  $n = 5$ , no optimization:

Size of circuit is proportional to number of low-level bit-operations in all execution paths of adder.

## Example: Adder

$n$  is the integer-size in bits.

| <b>paper</b>                  | <b>ancillae</b> | <b>size</b>              |
|-------------------------------|-----------------|--------------------------|
| VBE (1995)                    | $n$             | $\sim 8n$                |
| Cuccaro, Drapper & al. (2005) | 0               | $\sim 7n$                |
| Drapper, Kutin & al. (2008)   | $\sim 2n$       | $\sim 10n$ (in place)    |
| Drapper, Kutin & al. (2008)   | $\sim n$        | $\sim 5n$ (not in place) |

How do we scale against these ?

## Example: Adders

If  $n = 5$ :

| <b>paper</b>                  | <b>ancillae</b> | <b>size</b>              |
|-------------------------------|-----------------|--------------------------|
| VE (1995)                     | 5               | $\sim 40$                |
| Cuccaro, Drapper & al. (2005) | 0               | $\sim 35$                |
| Drapper, Kutin & al. (2008)   | $\sim 10$       | $\sim 50$ (in place)     |
| Drapper, Kutin & al. (2008)   | $\sim 5$        | $\sim 50$ (not in place) |

Automatically generated (no optimization):

## Example: Adders

If  $n = 5$ :

| paper                         | ancillae  | size                     |
|-------------------------------|-----------|--------------------------|
| VBE (1995)                    | 5         | $\sim 40$                |
| Cuccaro, Drapper & al. (2005) | 0         | $\sim 35$                |
| Drapper, Kutin & al. (2008)   | $\sim 10$ | $\sim 50$ (in place)     |
| Drapper, Kutin & al. (2008)   | $\sim 5$  | $\sim 50$ (not in place) |

With a bit of (automated) optimization:

## Example: The vector $b$

Hand-made circuits for: adders, multipliers, comparison, square root.

How about the  $b$  vector of the QLS algorithm ( $Ax = b$ ) ?

It gives a program computing the circuit

- » Program well-typed
- » Size of circuit proportional to execution time
- » Compositional

# Oracle Synthesis Nowadays

A lot of progress! But not quite enough to get there  
See for example Gidney's blog:

For Shor's factoring algorithm, aiming at 21:

More broadly

- » Realm of FTQC
- » Large actors enters the field: Google, Microsoft, IBM, AWS. . .

# Goal

## Formalizing

- » Functional programming
- » Higher-order combinators
- » Capable of manipulating quantum information
- » And quantum circuits

## The first two items

- » Realm of lambda-calculus

# Lambda-Calculus

- » Formal system from Alonzo Church, ~1930
- » Concept of **Function** and **Application**
  - “**Every term is a function!**”
  - Core of **functional** programming
  - For example: Haskell, OCaml, F#, Lisp, Erlang, *etc.*
- » Very simple grammar:
  - Variables  $x_1, x_2, x_3, \dots$
  - Application (binary, infix)
  - **Abstraction**:  $\lambda x.t$  (where  $t$  is a term)
- »  $\lambda x.t$ : the function “ $x \mapsto t$ ”

- » Extension of a **first-order** system
  - Can be extended to other **first-order** symbols
  - Also to other **second-order** constructions (like  $\mu$ -calculus. . .)
  - But **universal**
- » Notation
  - $\lambda x.t_1 t_2 t_3 = \lambda x.((t_1 t_2) t_3)$
  - $\lambda xy.t = \lambda x.\lambda y.t$

# Lambda-Calculus

- » Notion of **bound** and **free** variables
- » In  $\lambda y.x(\lambda z.z)$ :
  - $x$  is free
  - $y, z$  are bound
- » Each bound variable is attached to a  $\lambda$ 
  - $\lambda z . x \lambda x . x ( \lambda x . x z )$
- » The name of bound variables does not matter
  - $\lambda x.x = \lambda y.y$
  - $\lambda xy.x (y z) = \lambda ab.a (b z)$
  - **Careful!**  $\lambda x.y \neq \lambda y.y$

# Rewriting Rules

- »  $\beta$ -reduction:  $(\lambda x.t)u \longrightarrow_{\beta} t[x := u]$   
(! only the  $x$  bound by the corresponding  $\lambda$  are replaced)
- » A rule that can be added:  
 $\eta$ -reduction:  $(\lambda x.tx) \longrightarrow_{\eta} t$   
(! when  $x$  is not free in  $t$ )
- » Congruence:  
Reduction can occur within a term  
If  $M \longrightarrow M'$ , then  $MN \longrightarrow M'N$   
(Context-free rules)

## Example

What are the behaviors of

»  $\Omega = (\lambda x.xx)(\lambda x.xx)$ ?

»  $ZZ V$  when  $Z = \lambda zx.x(zzx)$ ? (Turing's fixed point combinator)

Church numerals are defined as

»  $\bar{0} \triangleq \lambda xy.y$

»  $\bar{1} \triangleq \lambda xy.xy$

»  $\bar{2} \triangleq \lambda xy.x(xy)$

»  $\bar{3} \triangleq \lambda xy.x(x(xy))$

When fed with  $\bar{m}$  and  $\bar{n}$ , what are the behaviors of

»  $M = \lambda mn.\lambda xy.mx(nxy)$  ?

»  $N = \lambda mn.m(Mn)(\lambda xy.y)$  ?

Pure lambda calculus is Turing complete

## Link with Functional Programming

$(\lambda x.t)u$  can be interpreted as `let  $x = u$  in  $t$`

Example with

```
let a = 1 + 2 in  
let b = 5 * a * a in  
let f =  $\lambda x . a * x * x$  in f b
```

(Here we assume that we have integers available somehow)

# Evaluation Strategy

- » Imagine that “tic” evaluates to 0 while emitting... a tic.
- » Consider the term:

$$(\lambda x.xx)((\lambda yz.z) \text{tic})$$

- » How many tics does the term emit?

## Two standard strategies

- » No rewriting under  $\lambda$ 's
- » **Call by name**: “As far left as possible” / “As early as possible”  
This is called **lazy** evaluation  
→ Evaluation used in Haskell, for example
- » **Call by value**: “As far right as possible”  
Evaluation starts with the arguments  
→ The **standard** evaluation: OCaml, F#, etc.

# Call-by-Value

```
let a = 1 + 2 in  
let b = 5 * a * a in  
let f =  $\lambda x . a * x * x$  in f b
```

corresponds to the lambda term:

$$(\lambda a.(\lambda b.(\lambda f.fb)(\lambda x.a * x * x))(5 * a * a))(1 + 2)$$

Call by value evaluation:

$$\begin{aligned} &\rightarrow (\lambda a.(\lambda b.(\lambda f.fb)(\lambda x.a * x * x))(5 * a * a))3 \\ &\rightarrow (\lambda b.(\lambda f.fb)(\lambda x.3 * x * x))(5 * 3 * 3) \\ &\rightarrow (\lambda b.(\lambda f.fb)(\lambda x.3 * x * x))45 \\ &\rightarrow (\lambda f.f\ 45)(\lambda x.3 * x * x) \\ &\rightarrow (\lambda x.3 * x * x)45 \\ &\rightarrow 3 * 45 * 45 \\ &\rightarrow 6075 \end{aligned}$$

No reduction under lambdas

## Call-by-Value

```
let a = 1 + 2 in  
let b = 5 * a * a in  
let f =  $\lambda x . a * x * x$  in f b
```

corresponds to the code transformation

```
let a = 3 in  
let b = 5 * a * a in  
let f =  $\lambda x . a * x * x$  in f b
```

which rewrites to

```
let b = 5 * 3 * 3 in  
let f =  $\lambda x . 3 * x * x$  in f b
```

which rewrites to

```
let b = 45 in  
let f =  $\lambda x . 3 * x * x$  in f b
```

...

# Functional Purity

```
let a = 1 + 2 in  
let b = 5 * a * a in  
let f =  $\lambda x$  . a * x * x in  
let a = 0 in f b
```

The second a has nothing to do with the first one

- » Immutable variables
- » Notion of purely functional language
- » The environment does not affect the behavior of a function

# Functional Purity

```
let f = λx . λy . x * y in (f (1 + 2)) (3 + 4)
```

or

```
let f = λy . λx . x * y in (f (3 + 4)) (1 + 2)
```

The order of argument evaluation does not matter

- » First a then b, or the opposite
- » Again linked to functional purity

# Simple Type System

Similar to Emmanuel's minimal logic

$$A, B ::= \text{nat} \mid A \rightarrow B$$

with an **opaque type** `nat`.

## Intuition

- »  $\lambda x.M$  is typed with  $A \rightarrow B$  (if well-typed)
- » `2` is typed with `nat`
- » `+` is typed with `nat  $\rightarrow$  nat  $\rightarrow$  nat` (modulo infix notation)

# Simple Type System

## Typing context

$$x_1 : A_1, x_2 : A_2, \dots, x_n : A_n \vdash M : B$$

## Typing rules

$$\frac{\Delta, x : A \vdash M : B}{\Delta \vdash \lambda x. M : A \rightarrow B} \qquad \frac{\Delta \vdash M : A \rightarrow B \quad \Delta \vdash N : A}{\Delta \vdash MN : B}$$

$$\overline{\Delta, x : A \vdash x : A}$$

$$\overline{+ : \text{nat} \rightarrow \text{nat} \rightarrow \text{nat}} \qquad \overline{2 : \text{nat}} \qquad (\text{one for each } n)$$

# Simple Type System

Typing context

$$A_1, \quad A_2, \dots \quad A_n \vdash \quad B$$

Typing rules

$$\frac{\Delta, \quad A \vdash \quad B}{\Delta \vdash \quad A \rightarrow B} \quad \frac{\Delta \vdash \quad A \rightarrow B \quad \Delta \vdash \quad A}{\Delta \vdash \quad B}$$
$$\overline{\Delta, \quad A \vdash \quad A}$$

Curry-Howard correspondence: well-typed terms are proofs

# Extensions

**Example:** Pairing, Boolean values:

$$A, B ::= \text{nat} \mid A \rightarrow B \mid A \times B \mid \text{bit}$$

**Typing rules** with new term constructs

$$\begin{array}{c} \frac{\Delta, x : A \vdash M : B}{\Delta \vdash \lambda x. M : A \rightarrow B} \qquad \frac{\Delta \vdash M : A \rightarrow B \quad \Delta \vdash N : A}{\Delta \vdash MN : B} \\[2ex] \frac{\Delta \vdash M : A \quad \Delta \vdash N : B}{\Delta \vdash \langle M, N \rangle : A \times B} \qquad \frac{\Delta \vdash M : A_1 \times A_2}{\Delta \vdash \pi_i M : A_i} \\[2ex] \frac{\Delta \vdash P : \text{bit} \quad \Delta \vdash M, N : C}{\Delta \vdash \text{if } P \text{ then } M \text{ else } N : C} \qquad \frac{}{\Delta \vdash \text{true}, \text{false} : \text{bit}} \end{array}$$

## Safety Properties

- » **Subject reduction:** type is preserved by reduction
- » **Progress:** well-typed terms either reduce or reached a value

# One problem: Entanglement

Let us add

- » an opaque type `qbit`
- » constants  $|\phi\rangle$  for all possible states

We can do

$$\lambda f.(f\ |0\rangle)\ |1\rangle : (\text{qbit} \rightarrow \text{qbit} \rightarrow A) \rightarrow A$$

but what if the two states are entangled:

$$\lambda f.(fq_1)q_2 : (\text{qbit} \rightarrow \text{qbit} \rightarrow A) \rightarrow A$$

where  $q_1, q_2$  is in state  $\frac{1}{\sqrt{2}}(|00\rangle + |11\rangle)$  ?

# Quantum Lambda-Calculus

## Terms

- » Pairing constructs and fixpoints
- » Boolean true and false, if-then-else
- » Constant, opaque terms: qinit, measure, H, CNOT, ...
- » Quantum states **not** in the language  
→ included as **pointers**

## Operational semantics

- » Abstract machine encapsulating the quantum memory:

$$\left( \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle), \quad |xy\rangle, \quad \lambda f.f\langle x, y \rangle \right)$$

state vector                      “linking function”                      lambda-term

- » **Call-by-value** evaluation strategy  
(Reduction strategy linked to the type system!)
- » Quantum operations through the evaluation strategy

$$[\alpha |0\rangle + \beta |1\rangle, |x\rangle, \text{let } y = \text{qinit false in CNOT } \langle x, y \rangle]$$

reduces to

$$[\alpha |00\rangle + \beta |11\rangle, |xy\rangle, \langle x, y \rangle]$$

## Another Problem: Non-Duplicability

Consider the following

$$\left[ \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle), |x\rangle, \langle \text{meas } x, \text{had } x \rangle \right]$$

In a purely functional world, the order should not matter!

Notion of linear type system

- » Quantum data is non-duplicable
- » Type system based on linear logic

# Quantum Memory

## Mathematical Structure

- » Quantum register  $\equiv$  (finite) Hilbert space
- » Juxtaposition  $\equiv$  Kronecker (tensor) product
- » Reading  $\equiv$  measure  $\equiv$  getting a bit, probabilistic
- » Quantum information is **non-duplicable**

## Type Structure

- » Based on (Intuitionistic) Multiplicative Linear Logic

$$A, B ::= \text{qbit} \mid \text{bit} \mid A \otimes B$$

- » Entanglement:

$$\left[ \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle), |xy\rangle, \langle x, y| \right] : \text{qbit} \otimes \text{qbit}$$

# Quantum Memory

## Mathematical Structure

- » Quantum register  $\equiv$  (finite) Hilbert space
- » Juxtaposition  $\equiv$  Kronecker (tensor) product
- » Reading  $\equiv$  measure  $\equiv$  getting a bit, probabilistic
- » Quantum information is **non-duplicable**

## Type Structure

- » Based on (Intuitionistic) Multiplicative Linear Logic

$$A, B ::= \text{qbit} \mid \text{bit} \mid A \otimes B \mid A \multimap B$$

Type of linear functions

- » Entanglement:

$$\left[ \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle), |xy\rangle, \langle x, y| \right] : \text{qbit} \otimes \text{qbit}$$

# Linear Type System

## Core Typing Rules

$$\frac{\Delta, x : A \vdash M : B}{\Delta \vdash \lambda x. M : A \multimap B} \quad \frac{\Delta \vdash M : A \multimap B \quad \Gamma \vdash N : A}{\Delta, \Gamma \vdash MN : B}$$

$$\frac{\Delta \vdash M : A \quad \Gamma \vdash N : B}{\Delta, \Gamma \vdash \langle M, N \rangle : A \otimes B} \quad \frac{\Delta, x : A, y : B \vdash N : C \quad \Gamma \vdash M : A \otimes B}{\Delta, \Gamma \vdash \text{let } \langle x, y \rangle = M \text{ in } N : C}$$
$$\overline{x : A \vdash x : A}$$

- » Non-duplicability
- »  $\lambda x. \langle x, x \rangle$  is not typable

# Quantum Circuit Model

## In this model

- » Circuit  $\equiv$  pure function from input to output

1-qbit unitary     $\text{qbit} \multimap \text{qbit}$

2-qbit unitary     $\text{qbit} \otimes \text{qbit} \multimap \text{qbit} \otimes \text{qbit}$

measurement     $\text{qbit} \multimap \text{bit}$

initialization     $1 \multimap \text{qbit}$

discard     $\text{qbit} \multimap 1$

- » Vertical composition  $\equiv$  tensoring
- » Horizontal composition  $\equiv$  function composition
- » Abstracts away the notion of register

## Limitation

- » Difficult to implement combinators

# Entanglement of Functions

Example of higher-order entanglement: Teleportation

# Entanglement of Functions

Example of higher-order entanglement: Teleportation

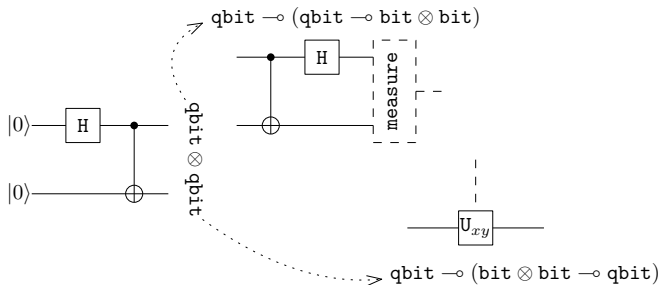

# Entanglement of Functions

## Example of higher-order entanglement: Teleportation

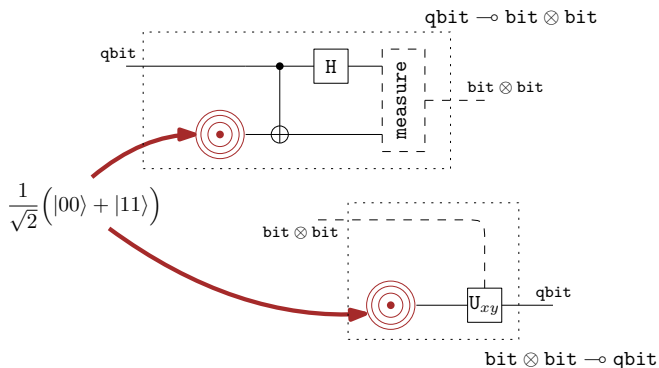

# Entanglement of Functions

## Example of higher-order entanglement: Teleportation

# Entanglement of Functions

## Example of higher-order entanglement: Teleportation

A pair of two entangled functions

$$(\text{qbit} \multimap \text{bit} \otimes \text{bit}) \otimes (\text{bit} \otimes \text{bit} \multimap \text{qbit})$$

inverses of each other.

# Typing Duplication

## A new type construct

$$A, B ::= \text{qbit} \mid \text{bit} \mid 1 \mid A \otimes B \mid A \multimap B \mid !A$$

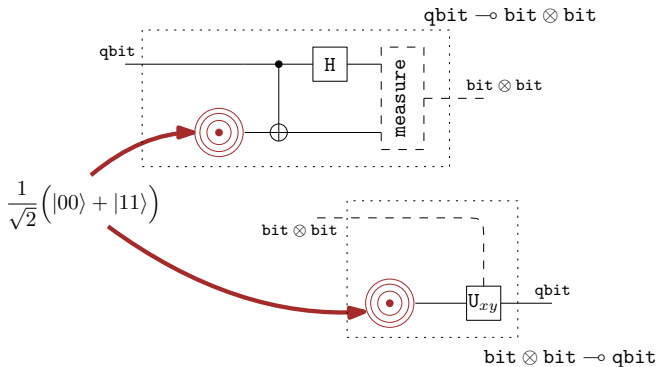

- » Based on linear logic
- » Non-duplicable functions with  $A \multimap B$
- » Duplicable functions with  $!(A \multimap B)$
- » Quantum operations are duplicable  
→ e.g.  $\text{measure} : !(\text{qbit} \multimap \text{bit})$

## Non-trivial mix

- » Classical and quantum data, probabilistic setting
- » Entanglement at higher-order

# Entanglement of Functions

## Example of higher-order entanglement: Teleportation

A pair of two entangled non-duplicable functions

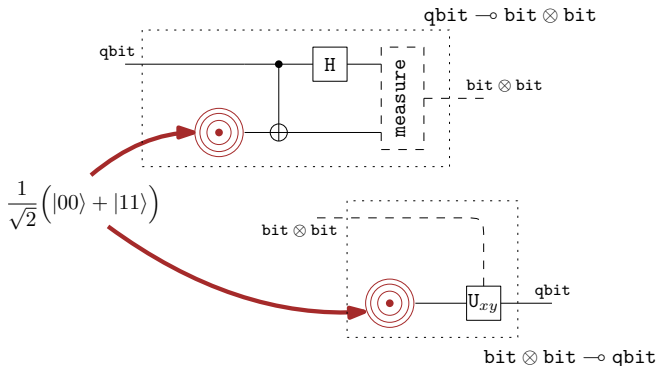

$$(\text{qbit} \mapsto \text{bit} \otimes \text{bit}) \otimes (\text{bit} \otimes \text{bit} \mapsto \text{qbit})$$

inverses of each other.

# Entanglement of Functions

## Example of higher-order entanglement: Teleportation

A duplicable procedure generating non-duplicable functions

$$!(1 \multimap (\text{qbit} \multimap \text{bit} \otimes \text{bit}) \otimes (\text{bit} \otimes \text{bit} \multimap \text{qbit}))$$

inverses of each other.

# Typing Duplication

## Core typing rules

$$\frac{!\Delta \vdash V : A}{!\Delta \vdash V : !A} (P) \quad \frac{\Delta \vdash M : !A}{\Delta \vdash M : A} (D)$$

$$\frac{\Delta, x : !A, y : !A \vdash M : B}{\Delta, x : !A \vdash M[y := x] : B} (C)$$

» Only values can be duplicated

(Call-by-value!)

## Examples

»  $\vdash \text{had}(\text{qinit true}) : !\text{qbit}$

(What is wrong?)

»  $\vdash \lambda x. \langle x, x \rangle : !A \multimap !A \otimes !A$

(Why?)

# Typing Duplication

Type these terms!

- » `true`
- » `λx.x`
- » `λx.(let z = H x in CNOT ⟨z, qinit false⟩)`
- » `H(qinit false)`
- » `⟨H(qinit false), λx.x⟩`
- » `let y = H(qinit false) in λf.f y`

Distinction between

- » Procedure for generating a qbit: duplicable
- » End result of the procedure: qbit value, non-duplicable

# Quantum Lambda-Calculus

## Bottom line

- » Classical data handled natively
- » Quantum data handled through pointers and instructions
- » Mix of duplicable and non-duplicable data, with higher-order

## Properties

- » Type system imposed as axioms
- » Safety properties derived “by hand”

(Could have used a realizability approach!)

## Limitations

- » Gates handled individually
- » Far from what is done in quantum algorithm
- » Need to consider an **extended circuit model**

# The problem

Naïve approach for typing combinators:

- » Repetition :  $\mathbb{N} \multimap (A \multimap A) \multimap (A \multimap A)$  (OK)
- » Inversion :  $(A \multimap B) \multimap (B \multimap A)$  (WRONG)
- » Control :  $(A \multimap B) \multimap (\text{qbit} \otimes A \multimap \text{qbit} \otimes B)$  (WRONG)

Does not work

- » Would require “reading” the gates.
- » But gates can only be sent to the QRAM

# Circuit Description Languages

## Extending the quantum $\lambda$ -calculus with

» A new opaque type for circuits:  $\text{Circ}(A, B)$

» Box and unbox constructions

$$(A \multimap B) \begin{array}{c} \xrightarrow{\text{box}} \\ \xleftarrow{\text{unbox}} \end{array} \text{Circ}(A, B)$$

— Box: instantiate a new circuit

— Unbox: evaluate a circuit

» A list of fixed, opaque circuits combinators such as

ctl :  $\text{Circ}(A, B) \multimap \text{Circ}(\text{qbit} \otimes A, \text{qbit} \otimes B)$

rev :  $\text{Circ}(A, B) \multimap \text{Circ}(B, A)$

» Nice arrow-like, categorical semantics

## Formalization of Quipper

» Proto-Quipper

» Notion of circuit-description language

# Circuit Description Languages

## Possible extensions

- » Inductive types (such as lists)
- » First-order quantifiers  
→ limited to “classical types”

## Dependent Proto-Quipper

- » Type  $[A]_n$  for lists of length  $n$  made of elements of type  $A$
- » In general,  $B(n)$  is a type parameterized by  $n$
- »  $f : \forall n : \mathbb{N} . B(n) \rightarrow A$  : function  $A$  to  $B$ , with  $f(n)$  of type  $B(n)$

## Examples

- »  $\forall n : \mathbb{N} . \text{Circ}([qbit]_n, [qbit]_n)$
- »  $\forall m, n : \mathbb{N} . [[qbit]_m]_n \multimap [qbit]_{mn}$

## Summary

- » Circuits are now first-order citizens
- » Close to what is done for “real algorithms”
- » Suitable for formalization and extensions

[LINDENHOVIUS, MISLOVE, ZAMDZHEV, 2018] [FU, SELINGER ET AL, 2020, 2022, 2024] [LEE, V ET AL, 2021] [COLLEDAN, DAL LAGO, 2025]

## Limitations

- » Circuits are built from opaque boxes
- » The only control is classical

# Notion of Control Flow

## Control flow in quantum computation

has two meanings

- » The control of a gate
- » The (classical) control-flow of the program:

# Quantum SWITCH

Are circuits “complete” ?

- » Canonical model for “usual” quantum algorithms
- » But a circuit is **causally ordered**

The quantum SWITCH

- » One copy of  $\boxed{U}$  and  $\boxed{V}$
- » Want a device with two wires  $x$  and  $y$  doing

$\boxed{U} \boxed{V}$  on  $y$  if  $x$  is 0

$\boxed{V} \boxed{U}$  on  $y$  if  $x$  is 1

# Quantum SWITCH

## Implementation with quantum photonics

- » Single photon
- » Control qubit as polarization

# Quantum SWITCH

## Implementation with quantum photonics

- » Single photon
- » Control qubit as polarization

Vertical polarization: goes through and yields  $V$  then  $U$ .

# Quantum SWITCH

## Implementation with quantum photonics

- » Single photon
- » Control qubit as polarization

Horizontal polarization: bounce and yields  $U$  then  $V$ .

# Quantum SWITCH

## Quantum Circuit for the quantum SWITCH

- » When  $U$  and  $V$  are duplicable:

$$! \text{Circ}(\text{qbit}, \text{qbit}) \multimap ! \text{Circ}(\text{qbit}, \text{qbit}) \multimap \text{Circ}(\text{qbit}, \text{qbit})$$

- » Realized with

- » What if they are not duplicable?

$$\text{Circ}(\text{qbit}, \text{qbit}) \multimap \text{Circ}(\text{qbit}, \text{qbit}) \multimap \text{Circ}(\text{qbit}, \text{qbit})$$

- » Doable with photonics

[CHIRIBELLA,D'ARIANO,PERINOTTI,V] [ORESHKOV,COSTA,BRUKNER]

- » But no satisfactory notion of quantum circuit

[CHIRIBELLA,D'ARIANO,PERINOTTI,V,2013]

# The problem

## Building circuit combinators

- » Quantum SWITCH as a primitive circuit combinator
- » But not really satisfactory!
- » How to **program** circuit combinators?

## The circuit construction is CLASSICAL

- » Instantiated on **one particular set of qubits**
- » Applied **regardless of the state of the memory.**
- » The type  $\text{Circ}(A, B)$  and the circuit combinators are
  - **opaque, non-programmable**
  - **flow of gates classically fixed**

## Trying to build circuit combinators

- » requires the non-available **quantum control**
- » quantum control known to not play well with classical control

| Conclusion                                       | 128        |

The first successful attempt at implementing a quantum test:

input  $x, y \vdash \text{qif}^\circ x \text{ then } (x, U y) \text{ else } (x, V y)$

Perform  $U$  or  $V$  on  $y$  conditionally on  $x$  without measuring.

» A naïve compilation approach would do

- » if  $U$  and  $V$  are “orthogonal”, one can get rid of  $x$
- » The orthogonality property is limited, hard to state
- » But QML compiles down to circuits: fully quantum

[ALTENKIRCH&GRATTAGE,2005]

# van Tonder's Quantum $\lambda$ -Calculus

Programs in superposition: [VAN TONDER, 2004]

van Tonder defines a syntactic  $\lambda$ -calculus with

- »  $\lambda$ -terms stored in quantum registers

$$\left| (\lambda mn. \lambda xy. mx(nxy)) (\lambda xy. x(xy)) (\lambda xy. x(x(xy))) \right\rangle$$

- »  $\beta$ -reduction as unitary operation
- » Constants such as 0, 1 and  $H$ :

$$|H0\rangle \longrightarrow \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle).$$

The unitarity constraints are too strong

- » The terms in superpositions are morally the same
- » Turning the language into a purely classical one

# Linear algebraic lambda-calculi

A side track to overcome the issue

[ARRIGHI&DOWEK,2008],[DIAZCARO&AL]

- » Allow linear combinations of terms (aka “superposition”)
  - $\lambda x.M$  is an operator where  $M$  can be a linear combination
  - $N(\alpha V + \beta W) \rightarrow \alpha(NV) + \beta(NW)$
- » Relax the constraints on orthogonality and norm

Advantages

- » Full power of  $\lambda$ -calculus
- » The  $\beta$ -reduction works fine
- » Isolate and study separately problems and solutions

Inconvenient (for this talk)

- » Not completely quantum anymore:  
No unitarity nor compilation to circuits

# Approach using Realizability

## Based on the linear algebraic lambda-calculus

- » Types defined as **set of values**
- » `qbit` defined as  
“normalized superpositions of true and false”
- »  $A \rightarrow B$  defined as  
“all  $M$  such that whenever  $N$  realizes  $A$ ,  $MN$  realizes  $B$ ”
- » Types organically emerge from the operational semantics

## Discussion

- » Capture both **quantum control** and **classical control**
- » But unitarity is a global property of the term
- » and no clear correspondance with physical hardware

# Another approach: Reversible Pattern-Matching

## Reversible pattern matching

[SABRY, V, VIZZOTTO, 2018]

- » syntax for circuits with type constructors  $\oplus$  and  $\otimes$
- » tests using pattern-matching
- »  $\text{Circ}(a, b)$  becomes programmable: we use  $a \leftrightarrow b$  instead

## Following circuit-description languages we add

- » recursive types, e.g.  $[a] \equiv 1 \oplus (a \otimes [a])$
- » higher-order on isos :
  - iso-variables
  - boxes in circuits can be iso-variables
  - lambda-abstractions  $\lambda f. \{ \dots \}$  and application
  - fixpoints :  $\mu f. \{ \dots \}$
  - operational semantics: substitution and unfolding

## Termination

- » Fixpoints are required to terminate on all inputs

An iso describes a bijective map on the sets of values

## Another approach: Reversible Pattern-Matching

Example of “complex” program: the map operation

Let  $f : a \leftrightarrow b$ .

Define  $\text{map } f : [a] \leftrightarrow [b]$  as

$$\mu \mathbf{g}^{[a] \leftrightarrow [b]}. \left\{ \begin{array}{l} [] \quad \leftrightarrow \quad [] \\ h : t \quad \leftrightarrow \quad \text{do } \begin{array}{c} h - \boxed{f} - h' \\ t - \boxed{\mathbf{g}} - t' \end{array} \text{ return } h' : t' \end{array} \right\}$$

The combinator  $\text{map}$  is typed with

$$(a \leftrightarrow b) \rightarrow ([a] \leftrightarrow [b])$$

# Another approach: Reversible Pattern-Matching

Example of “complex” program: the map operation

Let  $f : a \leftrightarrow b$ .

Define  $\text{map } f : [a] \leftrightarrow [b]$  as

# Isos as Unitary Maps in $\ell^2(a)$

$\ell^2([\text{Bool}])$

- » Hilbert space
- » Basis: all possible lists of Boolean values

For example

Consider map `Had` of type  $[\text{Bool}] \leftrightarrow [\text{Bool}]$  defined as

$$\mu_{\mathbf{g}}^{[\text{Bool}] \leftrightarrow [\text{Bool}]} \cdot \left\{ \begin{array}{l} [] \leftrightarrow [] \\ h : t \leftrightarrow \text{do } \begin{array}{c} h \text{---} \boxed{\text{Had}} \text{---} h' \\ t \text{---} \boxed{\mathbf{g}} \text{---} t' \end{array} \text{ return } h' : t' \end{array} \right\}$$

with

$$\text{Had} = \left\{ \begin{array}{l} \text{true} \leftrightarrow \frac{1}{\sqrt{2}} \cdot \text{true} + \frac{1}{\sqrt{2}} \cdot \text{false} \\ \text{false} \leftrightarrow \frac{1}{\sqrt{2}} \cdot \text{true} - \frac{1}{\sqrt{2}} \cdot \text{false} \end{array} \right\}$$

# Isos as Unitary Maps in $\ell^2(a)$

For example

Apply mapHad of type  $[\text{Bool}] \leftrightarrow [\text{Bool}]$  on

$$\frac{1}{\sqrt{2}}[\text{true}] + \frac{1}{\sqrt{2}}[\text{true}, \text{true}, \text{true}]$$

and get

A syntactic superposition of executions

## State of the Union

- » Quantum control is on the way!
- » Curry-Howard correspondence in progress  
[CHARDONNET, SAURIN, V, 2023] [CHARDONNET, LEMMONIER, V, 2023]
- » Interaction quantum/classical in progress  
[DAVE, LEMONNIER, PÉCHOUX, ZANDZHIEV, 2025]
- » Efficient compilation process in progress  
[HAINRY, PÉCHOUX, SILVA, 2023+2024]
- » Expressive type systems (dependent, etc) still missing.

# Conclusion: Quantum Programming Language

## Practical aspect

- » Coding quantum algorithms!
- » Design choices for quantum circuit-description
- » Monadic approach, amenable to oracle synthesis

## Theoretical aspect

- » Foundational work: quantum lambda-calculus
- » Type system based on linear logic
- » Extensions to capture circuit-description
- » Expressing quantum control still WIP
